

Exp- 19 Planet Knowledge Representation

Program:

```
planets = {  
    "mercury": "Closest planet to the Sun",  
    "venus": "Hottest planet",  
    "earth": "Supports life",  
    "mars": "Known as the Red Planet",  
    "jupiter": "Largest planet",  
    "saturn": "Has prominent rings",  
    "uranus": "Rotates on its side",  
    "neptune": "Farthest planet from the Sun"  
}  
  
planet = input("Enter planet name: ").lower()  
  
if planet in planets:  
    print(planets[planet])  
  
else:  
    print("Planet not found.")
```

Output:

The screenshot displays a Python IDE with two windows. The left window, titled 'Exp-19 # Planet Knowledge Representation.py', contains the source code for the program. The right window, titled 'IDLE Shell 3.13.5', shows the execution output. The code defines a dictionary of planets and their characteristics, prompts the user for a planet name, and prints the corresponding description or a 'not found' message. The output shows the user entered 'mars', and the program correctly printed 'Known as the Red Planet'.
