

Exp- 16 Birds Fly Knowledge Base

Program:

```
birds = {  
    "sparrow": True,  
    "parrot": True,  
    "penguin": False,  
    "ostrich": False  
}  
  
bird = input("Enter bird name: ").lower()  
  
if bird in birds:  
    if birds[bird]:  
        print(bird, "can fly.")  
    else:  
        print(bird, "cannot fly.")  
else:  
    print("Bird not found in knowledge base.")
```

Output:

The screenshot displays a Python IDE with two windows. The left window, titled 'Exp-16 Birds Fly Knowledge Base.py', contains the Python code for the knowledge base. The right window, titled 'IDLE Shell 3.13.5', shows the execution output. The code defines a dictionary 'birds' with keys 'sparrow', 'parrot', 'penguin', and 'ostrich', each mapped to a boolean value. It then prompts the user to enter a bird name, which is converted to lowercase. An if-else statement checks if the entered bird name is in the dictionary and if its corresponding value is True. If both conditions are met, it prints the bird name followed by 'can fly.'. Otherwise, it prints the bird name followed by 'cannot fly.'. If the bird name is not in the dictionary, it prints 'Bird not found in knowledge base.'.

```
birds = {  
    "sparrow": True,  
    "parrot": True,  
    "penguin": False,  
    "ostrich": False  
}  
  
bird = input("Enter bird name: ").lower()  
  
if bird in birds:  
    if birds[bird]:  
        print(bird, "can fly.")  
    else:  
        print(bird, "cannot fly.")  
else:  
    print("Bird not found in knowledge base.")
```
